1. What is the value of the expression at the bottom of the code? (Remember that NOT has the highest precedence, then AND, then OR. If op1 has higher precedence than op2, then "a op1 b op2 c" will be interpreted as "(a op1 b) op2 c".)

```
a = True
b = False
c = True
not a and b or c
```

Answer: A

```
(((not a) and b) or c) == (((not True) and False) or True) == True.
```

But we can also take the shortcut of noting that because c is True, the left side of the OR is irrelevant (anything OR True == True), making the entire expression True.
