1. What will the following code print when invoked as `mystery(10, 2)`?
   ```python
def mystery(a=1, b=3, c=6):
    print(a + 2 * b + c)
```
   A  11  
   B  13  
   C  20  
   D  22  

2. What will the following code print when invoked as `mystery(10, 2)`?
   ```python
def mystery(a=1, b=3, c=6):
    print(a + 2 * b + c)
```
   A  11  
   B  13  
   C  20  
   D  22  

   `mystery(10, 2)` is equivalent to `mystery(10, 2, 6)` where the third argument `c` is using the default value specified in the function header. Thus the answer is C.
