

Learning Goals

- Describe typical properties of greedy algorithms + key words:
"Objective Function", "Completion Time", "Optimization Problem",
"Greedy Ordering", "Optimal ordering", "Scoring Function"
- Create counterexample for a greedy ordering algorithm [G1]

Greedy Algorithm (informal def): an alg that sequentially constructs a solution through a series of myopic (short-sighted = local = not global = not thinking about future) decisions

Typical properties

- Easy to create
- Runtime easy to analyze
- Frequently not optimal
- When optimal, hard to prove correctness

Scheduling Tasks "optimization problem"

Input: n tasks: time, weight for each

task	1	2	3
time	3	4	2
weight	5	1	2

larger = more important
↑

Output: Order σ that minimizes

$$t_1 = 3 \quad w_3 = 2$$

"objective function" $\rightarrow A(\sigma) = \sum_{i=1}^n w_i C_i(\sigma)$

$$\sigma \in \underbrace{\{(123), (213), \dots\}}_{3!}$$

Applications: CPU scheduling, HW schedules

$C_i(\sigma)$ = completion time of task i w/ ordering σ

Brute Force $\Omega(n!)$

ex:

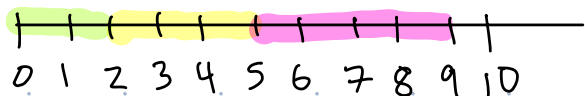

task	1	2	3
time	3	4	2

$$\sigma = (3, 1, 2)$$

$$C_1(3, 1, 2) = 5$$

$$C_2(3, 1, 2) = 9$$

$$C_3(3, 1, 2) = 2$$

What is $C_3(2, 1, 3)$?

- A) 2 B) 3 C) 7 **D) 9**

Calculate $A(\sigma)$ + determine best order: (Brute force)

task	1	2
time	3	4
weight	5	1

Order	(1,2)	(2,1)
$A(\sigma)$	22	39

Order	(1,2)	(2,1)
$C_1(\sigma)$	3	7
$C_2(\sigma)$	7	4

$$A(\sigma) = \sum_{i=1}^n w_i C_i(\sigma)$$

$$5 \cdot 3 + 1 \cdot 7 = 22$$

$$1 \cdot 4 + 5 \cdot 7 = 39$$

What is this objective function optimizing? What time/weight jobs is it prioritizing?

Output: Ordering σ that minimizes

$$A(\sigma) = \sum_{i=1}^n w_i C_i(\sigma)$$

Creating Scoring Functions + Counterexamples

Creating a greedy algorithm

To create, come up with any function $f(i)$ of i, w_i, t_i .

$$f(i) = t_i - 6 \quad (\text{order in increasing order})$$

↑ scoring function

task	1	2
time	3	4
weight	5	1
f	-3	-2

We did brute force above, found (1,2) is best

⇒ Greedy Ordering = (1,2)

↑
Optimal Ordering

But will this greedy ordering always be correct? [G1]

Try to find a counterexample:

- Think extreme!
- Create tasks close in score but different otherwise

$$f(i) = t_i - b(\text{increasing})$$

task	1	2
time	1	2
weight	1	100
f	-5	-4

→ Greedy Ordering (1,2)

Order	(1,2)	(2,1)
$A(\sigma)$	301	203

Opt. Ordering (2,1)

Counterexample

Group Exercise [G1]

Create counterexamples for scoring functions

A) $f(i) = w_i$ (decreasing) B) $f(i) = w_i - t_i$ (decreasing)

A)

task	1	2
time	1000	1
weight	2	1
f	2	1

→ (1, 2)

Brute force:

Order	(1,2)	(2,1)
A(σ)	3001	2003

Optimal: (2, 1)

B)

task	1	2
time		
weight		
f		

Brute force

Order	(1,2)	(2,1)
A(σ)		

Optimal:

One approach to designing greedy alg:

- create several reasonable scoring functions

- test, try to create counterexamples

- if no counter example, try to prove correct, or just use (heuristic)

$$w_i - t_i$$

$$w_i / t_i$$

$$w_i^2 - 2t_i$$

Thm: Ordering jobs by $f = \frac{w_i}{t_i}$ (decreasing) is optimal
for minimizing $A(\sigma) = \sum_i w_i C_i(\sigma)$.

Pf: [Exchange Argument]

ex: $\sigma^* = (3, 1, 2)$.

What is b, y in this example?

A) $b = 1$
 $y = 3$

B) $b = 3$
 $y = 1$

C) $b = 2$
 $y = 3$

D) No unique
 b, y

Let σ^{*1} be the same sequence as σ^* , but with b, y exchanged to be in the correct order

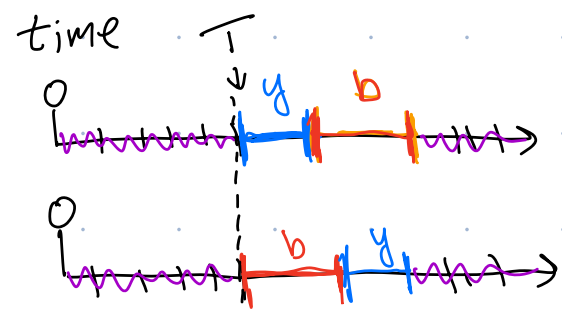

$\sigma^* =$

$\sigma^* = (3, 1, 2)$

$\sigma^{*1} =$

$\sigma^{*1} = (\quad)$

What is $A(\sigma^*) - A(\sigma^{*1})$? $(A(\sigma) = \sum_{i=1}^n w_i C_i(\sigma))$ Show ≥ 0 .

σ^*

σ^{*1}

$\sigma^*(i) = i^{\text{th}}$ job in ordering σ^*

$$A(\sigma^*) - A(\sigma^{*'}) =$$

$$\frac{A(\sigma^*) - A(\sigma^{*'})}{t_y t_b} =$$

$$\frac{A(\sigma^*) - A(\sigma^{*'})}{t_y t_b}$$

$$A(\sigma^*) - A(\sigma^{*'})$$

Divide both sides by $t_y t_b$:

But $b < y$, so $\frac{w_b}{t_b} \geq \frac{w_y}{t_y}$, so

, and $t_y, t_b > 0$, so

, and thus
